Abstract

1 To be completed...

2 1 Introduction

3 Deep neural network has achieved the state-of-the-art learning performance on numerous AI appli-
4 cations, e.g., computer vision [18, 22, 42], Natural Language Processing [20, 48, 49], Reinforcement
5 Learning [34, 40] and recommendation systems [12, 44]. With the increasing size of both data and
6 deep networks, standard single machine training confronts with at least two major challenges:

- 7 • Due to the limited computing power of a single machine, it would take a long time to
8 process the massive number of data samples—training would be slow.
- 9 • In many practical scenarios, data are typically stored in multiple servers, possibly at differ-
10 ent locations, due to the storage constraints (massive user behavior data, Internet images,
11 etc.) or privacy reasons [8]. Transmitting data might be costly.

12 *Distributed learning* framework [14] has been a common training strategy to tackle the above two
13 issues. For example, in distributed stochastic gradient descent (SGD) protocol, data are located at
14 N local nodes, at which the gradients of the model are computed in parallel. In each iteration,
15 a central server aggregates the local gradients, updates the global model, and transmits back the
16 updated model to the local nodes for subsequent gradient computation. As we can see, this setting
17 naturally solves aforementioned issues: 1) We use N computing nodes to train the model, so the
18 time per training epoch can be largely reduced; 2) There is no need to transmit the local data to
19 central server. Besides, distributed training also provides stronger error tolerance since the training
20 process could continue even one local machine breaks down. As a result of these advantages, there
21 has been a surge of study and applications on distributed systems [7, 36, 15, 19, 23, 31, 30].

22 Among many optimization strategies, SGD is still the most popular prototype in distributed training
23 for its simplicity and effectiveness [1, 46, 33]. Yet, when the deep learning model is very large, the
24 communication between local nodes and central server could be expensive. Burdensome gradient
25 transmission would slow down the whole training system, or even be impossible because of the lim-
26 ited bandwidth in some applications. Thus, reducing the communication cost in distributed SGD has
27 become an active topic, and an important ingredient of large-scale distributed systems (e.g. [38]).
28 Solutions based on quantization, sparsification and other compression techniques of the local gra-
29 dients are proposed [3, 45, 26, 43, 21, 10, 25, 41, 2, 5, 13, 47, 24]. As one would expect, in most
30 approaches, there exists a trade-off between compression and model accuracy. In particular, larger
31 bias of the compressed gradients usually brings more significant performance downgrade. Interest-
32 ingly, [28] shows that the technique of *error feedback* is able to remedy the issue of such biased
33 compressors, achieving same convergence rate and learning performance as full-gradient SGD.

34 On the other hand, in recent years, adaptive optimization algorithms (e.g. AdaGrad [16], Adam [29]
35 and AMSGrad [37]) have become popular because of their superior empirical performance. These

36 methods use different implicit learning rates for different coordinates that keep changing adaptively
 37 throughout the training process, based on the learning trajectory. In many learning problems, adap-
 38 tive methods have been shown to converge faster than SGD, sometimes with better generalization
 39 as well. However, the body of literature that combines adaptive methods with distributed training is
 40 still very limited.

41 1.1 Our contributions

42 2 Related Work

43 Sparse Optimization Methods.

44 **Distributed Learning.** When a large number of compute engines is available, being able to
 45 train global machine learning models while mutualizing the available and *decentralized* source of
 46 computation has been a growing focus for the community.

47 Decentralized optimization methods include methods such as ADMM [7], Distributed Subgradient
 48 Descent [36], Dual Averaging [15], Prox-PDA [23], GNSD [31], and Choco-SGD [30].

49 A recent work [9], which focuses on adaptive gradient methods, namely the Adam [29] and the
 50 AMSGrad [37] optimization methods, develops a decentralized variant of gradient based and adap-
 51 tive methods in the context of gossip protocols. To date, very few contributions provided attempt
 52 to efficiently run adaptive gradient method in such a distributed setting. Apart from [9], (author?)
 53 [35] proposes a decentralized version of AMSGrad [37] which provably satisfies some non-standard
 54 regret. Though, no sparsified variants of them have been proposed for practical purposes nor been
 55 studied in the literature.

56 **Compression-Based Distributed Optimization.** While the capabilities of the compute powers
 57 is exploding, the communication complexity between either the central server and the decentralized
 58 workers or among workers is becoming ineffectively large [11, 32]. Gradient sparsification con-
 59 stitutes one popular method to induce sparsity through the optimization procedure and reduce the
 60 number of bits transmitted at each iteration. Extensive works have studied this technique to improve
 61 the communication efficiency of SGD-based methods such as distributed SGD. This large class of
 62 sparsification techniques include gradient quantization leveraging quantized vector of gradients in
 63 the communication phase [3, 45, 26, 43, 21, 10, 25], gradient sparsification generally selection top
 64 k components of the vector to be communicated, see [41, 2], or variants of the particular SGD al-
 65 gorithm such as low-precision SGD [5, 28] proposing a trade-off between communication cost and
 66 precision, and signSGD [13, 47] where only the signs of the gradient vectors are communicated.
 67 Most of these works apply to the SGD method [6] as a prototype where a novel method and some
 68 convergence results are presented with a rate of $\mathcal{O}(\frac{1}{\sqrt{T}})$ where T denotes the total number of itera-
 69 tions, see [4], thus achieving the same rate as plain SGD, see [17, 27].

70 Yet these communication reduction techniques, still presents a negative dependence on the number
 71 of workers, typically a linear dependence. Hence the need for even more efficient techniques which
 72 constitutes the object of our paper.

73 3 Method

74 Most modern machine learning tasks can be casted as a large finite-sum optimization problem writ-
 75 ten as:

$$\min_{\theta \in \Theta} \frac{1}{n} \sum_{i=1}^n f_i(\theta) \quad (1)$$

76 where n denotes the number of workers, f_i represents the average loss for worker i and θ the global
 77 model parameter taking value in Θ , a subset of \mathbb{R}^d .

78 Some related work:

79 [28] develops variant of signSGD (as a biased compression schemes) for distributed optimization.
 80 Contributions are mainly on this error feedback variant. In [39], the authors provide theoretical

81 results on the convergence of sparse Gradient SGD for distributed optimization (we want that for
 82 AMS here). [41] develops a variant of distributed SGD with sparse gradients too. Contributions
 83 include a memory term used while compressing the gradient (using top k for instance). Speeding up
 84 the convergence in $\frac{1}{T^3}$.

85 Consider standard synchronous distributed optimization setting. AMSGrad is used as the prototype,
 86 and the local workers is only in charge of gradient computation.

87 3.1 TopK AMSGrad with Error Feedback

88 The key difference (and interesting part) of our TopK AMSGrad compared with the following arxiv
 89 paper “Quantized Adam” <https://arxiv.org/pdf/2004.14180.pdf> is that, in our model only
 90 gradients are transmitted. In “QAdam”, each local worker keeps a local copy of moment estimator
 91 m and v , and compresses and transmits m/v as a whole. Thus, that method is very much like the
 92 sparsified distributed SGD, except that g is changed into m/v . In our model, the moment estimates
 93 m and v are computed only at the central server, with the compressed gradients instead of the full
 94 gradient. This would be the key (and difficulty) in convergence analysis.

Algorithm 1 SPARS-AMS for Distributed Learning

```

1: Input: parameter  $\beta_1, \beta_2$ , learning rate  $\eta_t$ .
2: Initialize: central server parameter  $\theta_0 \in \Theta \subseteq \mathbb{R}^d$ ;  $e_{0,i} = 0$  the error accumulator for each
   worker; sparsity parameter  $k$ ;  $n$  local workers;  $m_0 = 0, v_0 = 0, \hat{v}_0 = 0$ 
3: for  $t = 1$  to  $T$  do
4:   parallel for worker  $i \in [n]$  do:
5:     Receive model parameter  $\theta_t$  from central server
6:     Compute stochastic gradient  $g_{t,i}$  at  $\theta_t$ 
7:     Compute  $\tilde{g}_{t,i} = \text{TopK}(g_{t,i} + e_{t,i}, k)$ 
8:     Update the error  $e_{t+1,i} = e_{t,i} + g_{t,i} - \tilde{g}_{t,i}$ 
9:     Send  $\tilde{g}_{t,i}$  back to central server
10:  end parallel
11:  Central server do:
12:     $\bar{g}_t = \frac{1}{n} \sum_{i=1}^n \tilde{g}_{t,i}$ 
13:     $m_t = \beta_1 m_{t-1} + (1 - \beta_1) \bar{g}_t$ 
14:     $v_t = \beta_2 v_{t-1} + (1 - \beta_2) \bar{g}_t^2$ 
15:     $\hat{v}_t = \max(v_t, \hat{v}_{t-1})$ 
16:    Update global model  $\theta_t = \theta_{t-1} - \eta_t \frac{m_t}{\sqrt{\hat{v}_t + \epsilon}}$ 
17: end for

```

95 3.2 Convergence Analysis

96 Several mild assumptions to make: Nonconvex and smooth loss function, unbiased stochastic gradi-
 97 ent, bounded variance of the gradient, bounded norm of the gradient, control of the distance between
 98 the true gradient and its sparse variant.

99 Check [9] starting with single machine and extending to distributed settings (several machines).

100 Under the distributed setting, the goal is to derive an upper bound to the second order moment of
 101 the gradient of the objective function at some iteration $T_f \in [1, T]$.

102 3.3 Mild Assumptions

103 We begin by making the following assumptions.

104 **A 1. (Smoothness)** For $i \in [n]$, f_i is L -smooth: $\|\nabla f_i(\theta) - \nabla f_i(\vartheta)\| \leq L \|\theta - \vartheta\|$.

105 **A 2. (Unbiased and Bounded gradient per worker)** For any iteration index $t > 0$ and worker index
 106 $i \in [n]$, the stochastic gradient is unbiased and bounded from above: $\mathbb{E}[g_{t,i}] = \nabla f_i(\theta_t)$ and
 107 $\|g_{t,i}\| \leq G_i$.

108 **A 3. (Bounded variance per worker)** For any iteration index $t > 0$ and worker index $i \in [n]$, the
 109 variance of the noisy gradient is bounded: $\mathbb{E}[|g_{t,i} - \nabla f_i(\theta_t)|^2] < \sigma_i^2$.

110 Denote by $Q(\cdot)$ the quantization operator Line 7 of Algorithm 1, which takes as input a gradient
 111 vector and returns a quantized version of it, and note $\tilde{g} := Q(g)$. Assume that

112 **A 4.** (Bounded Quantization) For any iteration $t > 0$, there exists a constant $q > 0$ such that
 113 $\|g_{t,i} - \tilde{g}_{t,i}\| \leq q \|g_{t,i}\|$, where $g_{t,i}$ is the stochastic gradient computed at iteration t for worker i .
 114 (high q means large quantization so loss of precision on the true gradient)

115 Denote for all $\theta \in \Theta$:

$$f(\theta) := \frac{1}{n} \sum_{i=1}^n f_i(\theta), \quad (2)$$

116 where n denotes the number of workers.

117 3.4 Intermediary Lemmas

118 **Lemma 1.** Under Assumption 2 and Assumption 4 we have for any iteration $t > 0$:

$$\|m_t\|^2 \leq (q^2 + 1)G^2 \quad \text{and} \quad \hat{v}_t \leq (q^2 + 1)G^2 \quad (3)$$

119 where m_t and $\hat{v}_t = \max(v_t, \hat{v}_{t-1})$ are defined Line 15 of Algorithm 1 and $G^2 = \frac{1}{n} \sum_{i=1}^N G_i^2$.

120 **Lemma 2.** Under A1 to A4, with a decreasing sequence of stepsize $\{\eta_t\}_{t>0}$, we have:

$$-\eta_{t+1} \mathbb{E}[\langle \nabla f(\theta_t) | (\hat{V}_{t+1} + \epsilon \mathbf{I}_d)^{-1/2} \bar{g}_t \rangle] \leq -\frac{\eta_{t+1}}{2} \left(\epsilon + \frac{(q^2 + 1)G^2}{1 - \beta_2} \right)^{-\frac{1}{2}} \mathbb{E}[\|\nabla f(\theta_t)\|^2] + q^2 \frac{G^2 \eta_{t+1}}{\epsilon 2n^2} \quad (4)$$

121 where \mathbf{I}_d is the identity matrix, \hat{V}_t the diagonal matrix which diagonal entries are $\hat{v}_t = \max(v_t, \hat{v}_{t-1})$
 122 defined Line 15 of Algorithm 1 and \bar{g}_t is the aggregation of all **quantized** gradients from the workers.

123 **Lemma 3.** Under A1 to A4, with a decreasing sequence of stepsize $\{\eta_t\}_{t>0}$, we have:

$$\begin{aligned} \mathbb{E}[f(\theta_{t+1}) - f(\theta_t)] &\leq -\frac{\eta_{t+1}(1 - \beta_1)}{2} \left(\epsilon + \frac{(q^2 + 1)G^2}{1 - \beta_2} \right)^{-\frac{1}{2}} \mathbb{E}[\|\nabla f(\theta_t)\|^2] + q^2 \frac{G^2 \eta_{t+1}}{\epsilon 2n^2} \\ &\quad - \eta_{t+1} \beta_1 \mathbb{E}[\langle \nabla f(\theta_{t-1}) | (\hat{V}_t + \epsilon \mathbf{I}_d)^{-1/2} m_t \rangle] \\ &\quad + \left(\frac{L}{2} + \beta_1 L \right) \|\theta_t - \theta_{t-1}\|^2 \\ &\quad + \eta_{t+1} G^2 \mathbb{E} \left[\sum_{j=1}^d \left[(\hat{v}_{t+1}^j + \epsilon)^{-1/2} - (\hat{v}_t^j + \epsilon)^{-1/2} \right] \right] \end{aligned} \quad (5)$$

124 where d denotes the dimension of the parameter vector

125 The main theorem in the decentralized setting reads:

126 **Theorem 1.** Under A1 to A4, with a constant stepsize $\eta_t = \eta = \frac{L}{\sqrt{T_m}}$, we have:

$$\frac{1}{T_m} \sum_{t=0}^{T_m-1} \mathbb{E}[\|\nabla f(\theta_t)\|^2] \leq \frac{\mathbb{E}[f(\theta_0) - f(\theta_{T_m})]}{L \Delta_1 \sqrt{T_m}} + d \frac{L \Delta_3}{\Delta_1 \sqrt{T_m}} + \frac{\Delta_2}{\eta \Delta_1 T_m} + \frac{1 - \beta_1}{\Delta_1} \epsilon^{-\frac{1}{2}} \sqrt{(q^2 + 1)G^2} \quad (6)$$

127 where

$$\begin{aligned} \Delta_1 &:= \frac{(1 - \beta_1)}{2} \left(\epsilon + \frac{(q^2 + 1)G^2}{1 - \beta_2} \right)^{-\frac{1}{2}} \quad , \quad \Delta_2 := q^2 + \sum_{k=t+1}^{\infty} \beta_1^{k-t+2} \frac{G^2}{\epsilon 2n^2} \\ \Delta_3 &:= \left(\frac{L}{2} + 1 + \frac{\beta_1 L}{1 - \beta_1} \right) (1 - \beta_2)^{-1} \left(1 - \frac{\beta_1^2}{\beta_2} \right)^{-1} \end{aligned} \quad (7)$$

We remark from this bound in Theorem 1, that the more quantization we apply to our gradient vectors ($q \uparrow$), the larger the upper bound of the stationary condition is, *i.e.*, the slower the algorithm is. This is intuitive as using compressed quantities will definitely impact the algorithm speed. We will observe in the numerical section below that a trade-off on the level of quantization q can be found to achieve similar speed of convergence with less computation resources used throughout the training.

Belhal Try for Single Machine Setting:

Define the auxiliary model

$$\begin{aligned}\theta'_{t+1} &:= \theta_{t+1} - e_{t+1} \\ &= \theta_t - \eta a_t - e_{t+1} \\ &= \theta_t - \eta a_t - e_t - g_t + \tilde{g}_t \\ &= \theta_t - \eta a_t - e_t - \Delta_t \\ &= \theta'_t - \eta a_t - \Delta_t\end{aligned}$$

where $a_t := \frac{m_t}{\sqrt{v_t + \epsilon}}$ and $\Delta_t := g_t - \tilde{g}_t$. By smoothness assumption we have

$$f(\theta'_{t+1}) \leq f(\theta'_t) - \langle \nabla f(\theta'_t), \eta a_t + \Delta_t \rangle + \frac{L}{2} \|\theta'_{t+1} - \theta'_t\|^2.$$

Thus,

$$\begin{aligned}\mathbb{E}[f(\theta'_{t+1}) - f(\theta'_t)] &\leq -\mathbb{E}[\langle \nabla f(\theta'_t), \eta a_t + \Delta_t \rangle] + \frac{L}{2} \mathbb{E}[\|\eta a_t + \Delta_t\|^2] \\ &\leq \eta \mathbb{E}[\langle \nabla f(\theta_t) - \nabla f(\theta'_t), \eta a_t + \Delta_t \rangle] - \mathbb{E}[\langle \nabla f(\theta_t), \eta a_t + \Delta_t \rangle] + \frac{L}{2} \mathbb{E}[\|\eta a_t + \Delta_t\|^2]\end{aligned}$$

Using the smoothness assumption A1 we have

$$\mathbb{E}[\langle \nabla f(\theta_t) - \nabla f(\theta'_t), \eta a_t + \Delta_t \rangle] \leq L \mathbb{E}[\|\theta_t - \theta'_t\|] \mathbb{E}[\|\eta a_t + \Delta_t\|]$$

Hence,

$$\begin{aligned}\mathbb{E}[f(\theta'_{t+1}) - f(\theta'_t)] &\leq -\mathbb{E}[\langle \nabla f(\theta'_t), \eta a_t + \Delta_t \rangle] + \frac{L}{2} \mathbb{E}[\|\eta a_t + \Delta_t\|^2] \\ &\leq -\left(\eta \frac{1}{\sqrt{G^2 + \epsilon}} + q\right) \mathbb{E}[\|\nabla f(\theta_t)\|^2] + L \mathbb{E}[\|\theta_t - \theta'_t\|] \mathbb{E}[\|\eta a_t + \Delta_t\|] + \frac{L}{2} \mathbb{E}[\|\eta a_t + \Delta_t\|^2] \\ &\leq -\left(\eta \frac{1}{\sqrt{G^2 + \epsilon}} + q\right) \mathbb{E}[\|\nabla f(\theta_t)\|^2] + L \mathbb{E}[\|e_t\| \|\eta a_t + \Delta_t\|] + \frac{L}{2} \mathbb{E}[\|\eta a_t + \Delta_t\|^2]\end{aligned}$$

Summing from $t = 0$ to $t = T_m - 1$ and divide it by T_m yields:

$$\begin{aligned}&\left(\eta \frac{1}{\sqrt{G^2 + \epsilon}} + q\right) \frac{1}{T_m} \sum_{t=0}^{T_m-1} \mathbb{E}[\|\nabla f(\theta_t)\|^2] \\ &\leq \sum_{t=0}^{T_m-1} \frac{\mathbb{E}[f(\theta'_t) - f(\theta'_{t+1})]}{T_m} + \frac{1}{T_m} \sum_{t=0}^{T_m-1} \mathbb{E}[\|e_t\| \|\eta a_t + \Delta_t\|] + \frac{L}{2T_m} \sum_{t=0}^{T_m-1} \mathbb{E}[\|\eta a_t + \Delta_t\|^2]\end{aligned}$$

Bounding $\frac{1}{T_m} \sum_{t=0}^{T_m-1} \mathbb{E}[\|e_t\| \|\eta a_t + \Delta_t\|]$:

To begin with

$$\begin{aligned}\|e_t\| &= \|e_{t-1} + g_{t-1} - \tilde{g}_{t-1}\| \\ &\leq q \|g_{t-1}\| + \|e_{t-1}\|\end{aligned}$$

Bounding $\frac{L}{2T_m} \sum_{t=0}^{T_m-1} \mathbb{E}[\|\eta a_t + \Delta_t\|^2]$:

144 4 Sequential Model

145 Single machine method

Algorithm 2 SPARS-AMS : Single machine setting

- 1: **Input:** parameter β_1, β_2 , learning rate η_t .
 - 2: Initialize: central server parameter $\theta_0 \in \Theta \subseteq \mathbb{R}^d$; $e_0 = 0$ the error accumulator; sparsity parameter k ; $m_0 = 0, v_0 = 0, \hat{v}_0 = 0$
 - 3: **for** $t = 1$ to T **do**
 - 4: Compute stochastic gradient $g_t = g_{t,i_t}$ at θ_t for randomly sampled index i_t
 - 5: Compute $\tilde{g}_t = \text{TopK}(g_t + e_t, k)$
 - 6: Update the error $e_{t+1} = e_t + g_t - \tilde{g}_t$
 - 7: $m_t = \beta_1 m_{t-1} + (1 - \beta_1) \tilde{g}_t$
 - 8: $v_t = \beta_2 v_{t-1} + (1 - \beta_2) \tilde{g}_t^2$
 - 9: $\hat{v}_t = \max(v_t, \hat{v}_{t-1})$
 - 10: Update global model $\theta_t = \theta_{t-1} - \eta_t \frac{m_t}{\sqrt{\hat{v}_t + \epsilon}}$
 - 11: **end for**
-

146 Let m'_t and \hat{v}'_t be the first and second moment moving average of standard AMSGrad using full
147 gradients. Denote

$$a_t = \frac{m_t}{\sqrt{\hat{v}_t + \epsilon}}, \quad a'_t = \frac{m'_t}{\sqrt{\hat{v}'_t + \epsilon}}.$$

148 Define the sequence

$$\mathcal{E}_{t+1} = \mathcal{E}_t + a'_t - a_t,$$

149 such that the auxiliary model

$$\begin{aligned} \theta'_{t+1} &:= \theta_{t+1} - \eta \mathcal{E}_{t+1} \\ &= \theta_t - \eta a_t - \eta \mathcal{E}_{t+1} \\ &= \theta_t - \eta a_t - \eta (\mathcal{E}_t + a'_t - a_t) \\ &= \theta'_t - \eta a'_t \end{aligned}$$

150 follows the update of full-gradient AMSGrad. By smoothness assumption we have

$$f(\theta'_{t+1}) \leq f(\theta'_t) - \eta \langle \nabla f(\theta'_t), a'_t \rangle + \frac{L}{2} \|\theta'_{t+1} - \theta'_t\|^2.$$

151 Thus,

$$\begin{aligned} \mathbb{E}[f(\theta'_{t+1}) - f(\theta'_t)] &\leq -\eta \mathbb{E}[\langle \nabla f(\theta'_t), a'_t \rangle] + \frac{\eta^2 L}{2} \mathbb{E}[\|a'_t\|^2] \\ &= -\eta \mathbb{E}[\langle \nabla f(\theta_t), a'_t \rangle] + \frac{\eta^2 L}{2} \mathbb{E}[\|a'_t\|^2] + \eta \mathbb{E}[\langle \nabla f(\theta_t) - \nabla f(\theta'_t), a'_t \rangle] \\ &\leq -\eta \mathbb{E}[\langle \nabla f(\theta_t), a'_t \rangle] + \frac{\eta^2 L}{2} \mathbb{E}[\|a'_t\|^2] + \eta \mathbb{E}[\frac{\eta^2 \rho}{2} \|\mathcal{E}_t\|^2 + \frac{1}{2\rho} \|a'_t\|^2] \\ &\leq -\eta \frac{\mathbb{E}\|\nabla f(\theta_t)\|^2}{\sqrt{G^2 + \epsilon}} + \frac{\eta}{2\rho} \frac{\mathbb{E}\|\nabla f(\theta_t)\|^2}{\epsilon} + \frac{\eta^2 L}{2} \mathbb{E}[\|a'_t\|^2] + \frac{\eta^3 \rho}{2} \mathbb{E}\|\mathcal{E}_t\|^2, \end{aligned}$$

152 when $\beta_1 = 0$ for example. We may discard this assumption and use more complicated bound on the
153 first two terms. The third term can be bounded by constant yielding $O(1/\sqrt{T})$ rate eventually when
154 taking decreasing learning rate. The key is to get a good bound on the cumulative error sequence,
155 \mathcal{E}_t . We have the following:

$$\begin{aligned} \mathbb{E}\|\mathcal{E}_{t+1}\|^2 &= \mathbb{E}\|\mathcal{E}_t + a'_t - a_t + \text{TopK}(\mathcal{E}_t + a'_t) - \text{TopK}(\mathcal{E}_t + a'_t)\|^2 \\ &\leq 2\mathbb{E}\|\mathcal{E}_t + a'_t - \text{TopK}(\mathcal{E}_t + a'_t)\|^2 + 2\mathbb{E}\|a_t - \text{TopK}(\mathcal{E}_t + a'_t)\|^2 \\ &\stackrel{(a)}{\leq} 2q\mathbb{E}\|\mathcal{E}_t + a'_t\| + 2\mathbb{E}\|a_t - \text{TopK}(\mathcal{E}_t + a'_t)\|^2 \\ &\leq 2q[(1+r)\mathbb{E}\|\mathcal{E}_t\|^2 + (1+\frac{1}{r})\mathbb{E}\|a'_t\|^2] + 2\mathbb{E}\|a_t - \text{TopK}(\mathcal{E}_t + a'_t)\|^2. \end{aligned}$$

156 where (a) uses A3. Current try: If we can bound the last term in the same form as the first two terms,
 157 then we can use recursion to get the desired result. We can have

$$\mathbb{E}\|a_t - \text{Top}K(\mathcal{E}_t + a'_t)\|^2 = \mathbb{E}\left\|\frac{\tilde{m}_t}{\sqrt{\hat{v}_t + \epsilon}} - \right\|^2$$

5 Experiments

Our proposed TopK-EF with AMSGrad matches that of full AMSGrad, in distributed learning. Number of local workers is 20. Error feedback fixes the convergence issue of using solely the TopK gradient.

Figure 1: Test accuracy.

314 A Appendix

315 B Proofs

316 B.1 Proof of Lemmas

317 **Lemma.** Under Assumption 2 and Assumption 4 we have for any iteration $t > 0$:

$$\|m_t\|^2 \leq (q^2 + 1)G^2 \quad \text{and} \quad \hat{v}_t \leq (q^2 + 1)G^2 \quad (8)$$

318 where m_t and $\hat{v}_t = \max(v_t, \hat{v}_{t-1})$ are defined Line 15 of Algorithm 1 and $G^2 = \frac{1}{n} \sum_{i=1}^N G_i^2$.

319 *Proof.* We start by writing

$$\|\bar{g}_t\|^2 = \left\| \frac{1}{n} \sum_{i=1}^N \tilde{g}_{t,i} \right\|^2 \leq \frac{1}{n} \sum_{i=1}^N \|\tilde{g}_{t,i}\|^2 \quad (9)$$

320 Though, using Assumption 2 and Assumption 4 we have:

$$\|\tilde{g}_{t,i}\|^2 = \|g_{t,i} + \tilde{g}_{t,i} - g_{t,i}\|^2 \leq \|g_{t,i}\|^2 + \|\tilde{g}_{t,i} - g_{t,i}\|^2 \leq (q^2 + 1)G_i^2 \quad (10)$$

321 Hence

$$\|\bar{g}_t\|^2 \leq (q^2 + 1)G^2 \quad (11)$$

322 where $G^2 = \frac{1}{n} \sum_{i=1}^N G_i^2$. Then, by construction in Algorithm 1:

$$\|m_t\|^2 \leq \beta_1^2 \|m_{t-1}\|^2 + (1 - \beta_1)^2 \|\bar{g}_t\|^2 \leq \beta_1^2 \|m_{t-1}\|^2 + (1 - \beta_1)^2 (q^2 + 1)G^2 \quad (12)$$

323 Since we have by initialization that $\|m_0\|^2 \leq G^2$, then we prove by induction that $\|m_t\|^2 \leq (q^2 + 1)G^2$.

325 Similarly

$$\hat{v}_t = \max(v_t, \hat{v}_{t-1}) = \max(\hat{v}_{t-1}, \beta_2 v_{t-1} + (1 - \beta_2) \bar{g}_t^2) \leq \max(\hat{v}_{t-1}, \beta_2 v_{t-1} + (1 - \beta_2)(q^2 + 1)G^2) \quad (13)$$

326 \square

327 **Lemma.** Under A1 to A4, with a decreasing sequence of stepsize $\{\eta_t\}_{t>0}$, we have:

$$-\eta_{t+1} \mathbb{E} \left[\left\langle \nabla f(\theta_t) \mid (\hat{V}_{t+1} + \epsilon \mathbf{I}_d)^{-1/2} \bar{g}_t \right\rangle \right] \leq -\frac{\eta_{t+1}}{2} \left(\epsilon + \frac{(q^2 + 1)G^2}{1 - \beta_2} \right)^{-\frac{1}{2}} \mathbb{E} [\|\nabla f(\theta_t)\|^2] + q^2 \frac{G^2 \eta_{t+1}}{\epsilon 2n^2} \quad (14)$$

328 where \mathbf{I}_d is the identity matrix, \hat{V}_t the diagonal matrix which diagonal entries are $\hat{v}_t = \max(v_t, \hat{v}_{t-1})$
329 defined Line 15 of Algorithm 1 and \bar{g}_t is the aggregation of all **quantized** gradients from the workers.

330 *Proof.* We first decompose \bar{g}_t as the sum of the unbiased stochastic gradients and its quantized
331 versions as computed Line 7 of Algorithm 1:

$$\bar{g}_t = \frac{1}{n} \sum_{i=1}^N \tilde{g}_{t,i} = \frac{1}{n} \sum_{i=1}^N [g_{t,i} + \tilde{g}_{t,i} - g_{t,i}] \quad (15)$$

332 Hence,

$$\begin{aligned} T_1 &:= -\eta_{t+1} \mathbb{E} \left[\left\langle \nabla f(\theta_t) \mid (\hat{V}_{t+1} + \epsilon \mathbf{I}_d)^{-1/2} \bar{g}_t \right\rangle \right] \\ &= \underbrace{-\eta_{t+1} \mathbb{E} \left[\left\langle \nabla f(\theta_t) \mid (\hat{V}_{t+1} + \epsilon \mathbf{I}_d)^{-1/2} \frac{1}{n} \sum_{i=1}^N g_{t,i} \right\rangle \right]}_{t_1} - \underbrace{\eta_{t+1} \mathbb{E} \left[\left\langle \nabla f(\theta_t) \mid (\hat{V}_{t+1} + \epsilon \mathbf{I}_d)^{-1/2} \frac{1}{n} \sum_{i=1}^N \tilde{g}_{t,i} - g_{t,i} \right\rangle \right]}_{t_2} \end{aligned} \quad (16)$$

333 **Bounding t_1 :** Using the Tower rule, we have:

$$\begin{aligned}
t_1 &:= -\eta_{t+1} \mathbb{E} \left[\left\langle \nabla f(\theta_t) \mid (\hat{V}_{t+1} + \epsilon \mathbf{I}_d)^{-1/2} \frac{1}{n} \sum_{i=1}^N g_{t,i} \right\rangle \right] \\
&= -\eta_{t+1} \mathbb{E} \left[\mathbb{E} \left[\left\langle \nabla f(\theta_t) \mid (\hat{V}_{t+1} + \epsilon \mathbf{I}_d)^{-1/2} \frac{1}{n} \sum_{i=1}^N g_{t,i} \right\rangle \mid \mathcal{F}_t \right] \right] \\
&= -\eta_{t+1} \mathbb{E} \left[\left\langle \nabla f(\theta_t) \mid (\hat{V}_{t+1} + \epsilon \mathbf{I}_d)^{-1/2} \mathbb{E} \left[\frac{1}{n} \sum_{i=1}^N g_{t,i} \mid \mathcal{F}_t \right] \right\rangle \right]
\end{aligned} \tag{17}$$

334 Using Assumption 2 and Lemma 1, we have that

$$\begin{aligned}
t_1 &:= -\eta_{t+1} \mathbb{E} \left[\left\langle \nabla f(\theta_t) \mid (\hat{V}_{t+1} + \epsilon \mathbf{I}_d)^{-1/2} \frac{1}{n} \sum_{i=1}^N g_{t,i} \right\rangle \right] \\
&\leq -\eta_{t+1} \left(\epsilon + \frac{(q^2 + 1)G^2}{1 - \beta_2} \right)^{-\frac{1}{2}} \mathbb{E} [\|\nabla f(\theta_t)\|^2]
\end{aligned} \tag{18}$$

335 **Bounding t_2 :**

336 We first recall Young's inequality with a constant $\delta \in (0, 1)$ as follows:

$$\langle X \mid Y \rangle \leq \frac{1}{\delta} \|X\|^2 + \delta \|Y\|^2. \tag{19}$$

337 Using Young's inequality (19) with parameter equal to 1:

$$\begin{aligned}
t_2 &\leq \frac{\eta_{t+1}}{2} \left(\epsilon + \frac{(q^2 + 1)G^2}{1 - \beta_2} \right)^{-\frac{1}{2}} \mathbb{E} [\|\nabla f(\theta_t)\|^2] + \frac{\eta_{t+1}}{2n^2} \mathbb{E} [(\hat{V}_{t+1} + \epsilon \mathbf{I}_d)^{-1/2} \sum_{i=1}^N \{\tilde{g}_{t,i} - g_{t,i}\}^2] \\
&\stackrel{(a)}{\leq} \frac{\eta_{t+1}}{2} \left(\epsilon + \frac{(q^2 + 1)G^2}{1 - \beta_2} \right)^{-\frac{1}{2}} \mathbb{E} [\|\nabla f(\theta_t)\|^2] + \frac{\eta_{t+1}}{2n^2} \mathbb{E} [(\hat{V}_{t+1} + \epsilon \mathbf{I}_d)^{-1/2}]^2 \sum_{i=1}^N \{\tilde{g}_{t,i} - g_{t,i}\}^2 \\
&\stackrel{(b)}{\leq} \frac{\eta_{t+1}}{2} \left(\epsilon + \frac{(q^2 + 1)G^2}{1 - \beta_2} \right)^{-\frac{1}{2}} \mathbb{E} [\|\nabla f(\theta_t)\|^2] + \frac{\eta_{t+1}}{2n^2} \mathbb{E} [(\hat{V}_{t+1} + \epsilon \mathbf{I}_d)^{-1/2}]^2 \mathbb{E} \left[\sum_{i=1}^N \{\tilde{g}_{t,i} - g_{t,i}\}^2 \right] \\
&\stackrel{(c)}{\leq} \frac{\eta_{t+1}}{2} \left(\epsilon + \frac{(q^2 + 1)G^2}{1 - \beta_2} \right)^{-\frac{1}{2}} \mathbb{E} [\|\nabla f(\theta_t)\|^2] + \frac{\eta_{t+1}}{\epsilon 2n^2} \mathbb{E} \left[\sum_{i=1}^N \tilde{g}_{t,i}^2 \right] \\
&\stackrel{(d)}{\leq} \frac{\eta_{t+1}}{2} \left(\epsilon + \frac{(q^2 + 1)G^2}{1 - \beta_2} \right)^{-\frac{1}{2}} \mathbb{E} [\|\nabla f(\theta_t)\|^2] + q^2 \frac{G^2 \eta_{t+1}}{\epsilon 2n^2}
\end{aligned} \tag{20}$$

338 where (a) uses the Cauchy-Schwartz inequality, (b) is due to the non-negativeness of both \hat{V}_{t+1}
339 and $\|\sum_{i=1}^N \{g_{t,i} + \tilde{g}_{t,i} - g_{t,i}\}\|^2$ and (c) uses the Triangle inequality. We use Assumption 3 and
340 Assumption 4 in (d).

341 Finally, combining (18) and (20) yields

$$-\eta_{t+1} \mathbb{E} \left[\left\langle \nabla f(\theta_t) \mid (\hat{V}_{t+1} + \epsilon \mathbf{I}_d)^{-1/2} \tilde{g}_t \right\rangle \right] \leq -\frac{\eta_{t+1}}{2} \left(\epsilon + \frac{(q^2 + 1)G^2}{1 - \beta_2} \right)^{-\frac{1}{2}} \mathbb{E} [\|\nabla f(\theta_t)\|^2] + q^2 \frac{G^2 \eta_{t+1}}{\epsilon 2n^2} \tag{21}$$

342 \square

343 **Lemma.** Under A1 to A4, with a decreasing sequence of stepsize $\{\eta_t\}_{t>0}$, we have:

$$\begin{aligned}
\mathbb{E}[f(\theta_{t+1}) - f(\theta_t)] &\leq -\frac{\eta_{t+1}(1 - \beta_1)}{2} \left(\epsilon + \frac{(q^2 + 1)G^2}{1 - \beta_2} \right)^{-\frac{1}{2}} \mathbb{E}[\|\nabla f(\theta_t)\|^2] + q^2 \frac{G^2 \eta_{t+1}}{\epsilon 2n^2} \\
&\quad - \eta_{t+1} \beta_1 \mathbb{E}[\langle \nabla f(\theta_{t-1}) | (\hat{V}_t + \epsilon \mathbf{I}_d)^{-1/2} m_t \rangle] \\
&\quad + \left(\frac{L}{2} + \beta_1 L \right) \|\theta_t - \theta_{t-1}\|^2 \\
&\quad + \eta_{t+1} G^2 \mathbb{E} \left[\sum_{j=1}^d \left[(\hat{v}_{t+1}^j + \epsilon)^{-1/2} - (\hat{v}_t^j + \epsilon)^{-1/2} \right] \right]
\end{aligned} \tag{22}$$

344 where d denotes the dimension of the parameter vector

345 *Proof.* Denote the following auxiliary variables at iteration $t + 1$

$$z_{t+1} = \theta_{t+1} + \frac{\beta_1}{1 - \beta_1} (\theta_{t+1} - \theta_t) \tag{23}$$

346 By assumption Assumption 1, we can write the smoothness condition on the overall objective (2),
347 between iteration t and $t + 1$:

$$f(\theta_{t+1}) \leq f(\theta_t) + \langle \nabla f(\theta_t) | \theta_{t+1} - \theta_t \rangle + \frac{L}{2} \|\theta_{t+1} - \theta_t\|^2 \tag{24}$$

348 Denote by \hat{V}_t the diagonal matrix which diagonal entries are $\hat{v}_t = \max(v_t, \hat{v}_{t-1})$ defined Line 15 of
349 Algorithm 1. Hence, we obtain,

$$f(\theta_{t+1}) \leq f(\theta_t) - \eta_{t+1} \langle \nabla f(\theta_t) | (\hat{V}_{t+1} + \epsilon \mathbf{I}_d)^{-1/2} m_{t+1} \rangle + \frac{L}{2} \|\theta_{t+1} - \theta_t\|^2 \tag{25}$$

350 where \mathbf{I}_d denotes the identity matrix.

351 We now take the expectation of those various terms conditioned on the filtration \mathcal{F}_t of the total
352 randomness up to iteration t .

$$\mathbb{E}[f(\theta_{t+1}) - f(\theta_t)] \leq -\eta_{t+1} \mathbb{E}[\langle \nabla f(\theta_t) | (\hat{V}_{t+1} + \epsilon \mathbf{I}_d)^{-1/2} m_{t+1} \rangle] + \frac{L}{2} \mathbb{E}[\|\theta_{t+1} - \theta_t\|^2] \tag{26}$$

353 We now focus on the computation of the inner product obtained in the equation above. We have

$$\begin{aligned}
&\eta_{t+1} \mathbb{E}[\langle \nabla f(\theta_t) | (\hat{V}_{t+1} + \epsilon \mathbf{I}_d)^{-1/2} m_{t+1} \rangle] \\
&= \eta_{t+1} \mathbb{E}[\langle \nabla f(\theta_t) | (\hat{V}_{t+1} + \epsilon \mathbf{I}_d)^{-1/2} m_{t+1} + (\hat{V}_t + \epsilon \mathbf{I}_d)^{-1/2} m_{t+1} - (\hat{V}_t + \epsilon \mathbf{I}_d)^{-1/2} m_{t+1} \rangle] \\
&= \eta_{t+1} \mathbb{E}[\langle \nabla f(\theta_t) | (\hat{V}_t + \epsilon \mathbf{I}_d)^{-1/2} m_{t+1} \rangle] + \eta_{t+1} \mathbb{E}[\langle \nabla f(\theta_t) | [(\hat{V}_{t+1} + \epsilon \mathbf{I}_d)^{-1/2} - (\hat{V}_t + \epsilon \mathbf{I}_d)^{-1/2}] m_{t+1} \rangle] \\
&= \eta_{t+1} \beta_1 \mathbb{E}[\langle \nabla f(\theta_t) | (\hat{V}_t + \epsilon \mathbf{I}_d)^{-1/2} m_t \rangle] + \eta_{t+1} (1 - \beta_1) \mathbb{E}[\langle \nabla f(\theta_t) | (\hat{V}_{t+1} + \epsilon \mathbf{I}_d)^{-1/2} \bar{g}_t \rangle] \\
&\quad + \eta_{t+1} \mathbb{E}[\langle \nabla f(\theta_t) | [(\hat{V}_{t+1} + \epsilon \mathbf{I}_d)^{-1/2} - (\hat{V}_t + \epsilon \mathbf{I}_d)^{-1/2}] m_{t+1} \rangle]
\end{aligned} \tag{28}$$

354 where \bar{g}_t is the aggregated gradients from all workers.

355 Plugging the above in (26) yields:

$$\begin{aligned}
& \mathbb{E}[f(\theta_{t+1}) - f(\theta_t)] \\
& \leq \underbrace{-\beta_1 \mathbb{E}[\langle \nabla f(\theta_t) | (\hat{V}_t + \epsilon \mathbf{I}_d)^{-1/2} m_t \rangle]}_{A_t} \eta_{t+1} \\
& \quad \underbrace{-\mathbb{E}[\langle \nabla f(\theta_t) | [(\hat{V}_{t+1} + \epsilon \mathbf{I}_d)^{-1/2} - (\hat{V}_t + \epsilon \mathbf{I}_d)^{-1/2}] m_{t+1} \rangle]}_{B_t} \eta_{t+1} \\
& \quad \underbrace{-(1 - \beta_1) \mathbb{E}[\langle \nabla f(\theta_t) | (\hat{V}_{t+1} + \epsilon \mathbf{I}_d)^{-1/2} \bar{g}_t \rangle]}_{C_t} \eta_{t+1} + \frac{L}{2} \mathbb{E}[\|\theta_{t+1} - \theta_t\|^2]
\end{aligned} \tag{29}$$

356 To begin with, by the tower rule, we have that

$$A_t = -\beta_1 \mathbb{E}[\mathbb{E}[\langle \nabla f(\theta_t) | (\hat{V}_t + \epsilon \mathbf{I}_d)^{-1/2} m_t \rangle | \mathcal{F}_t]] \tag{30}$$

$$= -\beta_1 \langle \nabla f(\theta_{t-1}) | (\hat{V}_t + \epsilon \mathbf{I}_d)^{-1/2} m_t \rangle - \beta_1 \langle \nabla f(\theta_t) - \nabla f(\theta_{t-1}) | (\hat{V}_t + \epsilon \mathbf{I}_d)^{-1/2} m_t \rangle \tag{31}$$

$$\tag{32}$$

where we recognize the first term as the term in (27), at iteration $t - 1$ and hence apply the same decomposition as in (28). Coupling with the smoothness of f , which gives that

$$-\beta_1 \langle \nabla f(\theta_t) - \nabla f(\theta_{t-1}) | (\hat{V}_t + \epsilon \mathbf{I}_d)^{-1/2} m_t \rangle \leq \frac{\beta_1 L}{\eta_{t-1}} \|\theta_t - \theta_{t-1}\|^2$$

357 we obtain,

$$\begin{aligned}
A_t &= -\beta_1 \mathbb{E}[\mathbb{E}[\langle \nabla f(\theta_t) | (\hat{V}_t + \epsilon \mathbf{I}_d)^{-1/2} m_t \rangle | \mathcal{F}_t]] \\
&\leq \eta_{t+1} \beta_1 (A_{t-1} + B_{t-1} + C_{t-1}) + \eta_{t+1} \frac{\beta_1 L}{\eta_{t-1}} \|\theta_t - \theta_{t-1}\|^2
\end{aligned} \tag{33}$$

358 Then,

$$\begin{aligned}
B_t &= -\mathbb{E}[\langle \nabla f(\theta_t) | [(\hat{V}_{t+1} + \epsilon \mathbf{I}_d)^{-1/2} - (\hat{V}_t + \epsilon \mathbf{I}_d)^{-1/2}] m_{t+1} \rangle] \\
&= \mathbb{E}[\sum_{j=1}^d \nabla^j f(\theta_t) m_{t+1}^j [(\hat{v}_{t+1}^j + \epsilon)^{-1/2} - (\hat{v}_t^j + \epsilon)^{-1/2}]] \\
&\stackrel{(a)}{\leq} \mathbb{E}[\|\nabla f(\theta_t)\| \|m_{t+1}\| \sum_{j=1}^d [(\hat{v}_{t+1}^j + \epsilon)^{-1/2} - (\hat{v}_t^j + \epsilon)^{-1/2}]] \\
&\stackrel{(b)}{\leq} G^2 \mathbb{E}[\sum_{j=1}^d [(\hat{v}_{t+1}^j + \epsilon)^{-1/2} - (\hat{v}_t^j + \epsilon)^{-1/2}]]
\end{aligned} \tag{34}$$

359 where $\nabla^j f(\theta_t)$ denotes the j -th component of the gradient vector $\nabla f(\theta_t)$, (a) uses of the Cauchy-
360 Schwartz inequality and (b) boils down from the norm of the gradient vector boundedness assump-
361 tion 2, denoting $G := \frac{1}{n} \sum_{i=1}^n G_i$.

362 Plugging the above into (29) yields

$$\begin{aligned}
\mathbb{E}[f(\theta_{t+1}) - f(\theta_t)] &\leq \eta_{t+1}(A_t + B_t + C_t) + \frac{L}{2}\mathbb{E}[\|\theta_{t+1} - \theta_t\|^2] \\
&\leq -\eta_{t+1}\beta_1\mathbb{E}[\langle \nabla f(\theta_{t-1}) | (\hat{V}_t + \epsilon \mathbf{I}_d)^{-1/2} m_t \rangle] \\
&\quad + \eta_{t+1}G^2\mathbb{E}\left[\sum_{j=1}^d \left[(\hat{v}_{t+1}^j + \epsilon)^{-1/2} - (\hat{v}_t^j + \epsilon)^{-1/2}\right]\right] \\
&\quad + \left(\frac{L}{2} + \eta_{t+1}\frac{\beta_1 L}{\eta_{t-1}}\right)\|\theta_t - \theta_{t-1}\|^2 \\
&\quad - \eta_{t+1}(1 - \beta_1)\mathbb{E}[\langle \nabla f(\theta_t) | (\hat{V}_{t+1} + \epsilon \mathbf{I}_d)^{-1/2} \bar{g}_t \rangle]
\end{aligned} \tag{35}$$

363 We bound the last term on the RHS, $-\eta_{t+1}\mathbb{E}[\langle \nabla f(\theta_t) | (\hat{V}_{t+1} + \epsilon \mathbf{I}_d)^{-1/2} \bar{g}_t \rangle]$ with Lemma 2

364 Under the assumption that we use a decreasing stepsize such that $\eta_{t+1} \leq \eta_t$, and given that according
365 to Line 15 we have that $\hat{v}_{t+1} \geq \hat{v}_t$ by construction, we obtain

$$\begin{aligned}
\mathbb{E}[f(\theta_{t+1}) - f(\theta_t)] &\leq -\frac{\eta_{t+1}(1 - \beta_1)}{2}\left(\epsilon + \frac{(q^2 + 1)G^2}{1 - \beta_2}\right)^{-\frac{1}{2}}\mathbb{E}[\|\nabla f(\theta_t)\|^2] + q^2\frac{G^2\eta_{t+1}}{\epsilon 2n^2} \\
&\quad - \eta_{t+1}\beta_1\mathbb{E}[\langle \nabla f(\theta_{t-1}) | (\hat{V}_t + \epsilon \mathbf{I}_d)^{-1/2} m_t \rangle] \\
&\quad + \left(\frac{L}{2} + \beta_1 L\right)\|\theta_t - \theta_{t-1}\|^2 \\
&\quad + \eta_{t+1}G^2\mathbb{E}\left[\sum_{j=1}^d \left[(\hat{v}_{t+1}^j + \epsilon)^{-1/2} - (\hat{v}_t^j + \epsilon)^{-1/2}\right]\right]
\end{aligned} \tag{36}$$

366 Finally, using Lemma 2, we obtain the desired result. \square

367 B.2 Proof of Theorem 1

368 **Theorem.** Under A1 to A4, with a constant stepsize $\eta_t = \eta = \frac{L}{\sqrt{T_m}}$, we have:

$$\frac{1}{T_m} \sum_{t=0}^{T_m-1} \mathbb{E}[\|\nabla f(\theta_t)\|^2] \leq \frac{\mathbb{E}[f(\theta_0) - f(\theta_{T_m})]}{L\Delta_1\sqrt{T_m}} + d\frac{L\Delta_3}{\Delta_1\sqrt{T_m}} + \frac{\Delta_2}{\eta\Delta_1 T_m} + \frac{1 - \beta_1}{\Delta_1}\epsilon^{-\frac{1}{2}}\sqrt{(q^2 + 1)}G^2 \tag{37}$$

369 where

$$\begin{aligned}
\Delta_1 &:= \frac{(1 - \beta_1)}{2}\left(\epsilon + \frac{(q^2 + 1)G^2}{1 - \beta_2}\right)^{-\frac{1}{2}}, \quad \Delta_2 := q^2 + \sum_{k=t+1}^{\infty} \beta_1^{k-t+2} \frac{G^2}{\epsilon 2n^2} \\
\Delta_3 &:= \left(\frac{L}{2} + 1 + \frac{\beta_1 L}{1 - \beta_1}\right)(1 - \beta_2)^{-1}\left(1 - \frac{\beta_1^2}{\beta_2}\right)^{-1}
\end{aligned} \tag{38}$$

370 *Proof.* By Lemma 3 we have

$$\begin{aligned}
\mathbb{E}[f(\theta_{t+1}) - f(\theta_t)] &\leq -\frac{\eta_{t+1}(1 - \beta_1)}{2}\left(\epsilon + \frac{(q^2 + 1)G^2}{1 - \beta_2}\right)^{-\frac{1}{2}}\mathbb{E}[\|\nabla f(\theta_t)\|^2] + q^2\frac{G^2\eta_{t+1}}{\epsilon 2n^2} \\
&\quad - \eta_{t+1}\beta_1\mathbb{E}[\langle \nabla f(\theta_{t-1}) | (\hat{V}_t + \epsilon \mathbf{I}_d)^{-1/2} m_t \rangle] \\
&\quad + \left(\frac{L}{2} + \beta_1 L\right)\|\theta_t - \theta_{t-1}\|^2 \\
&\quad + \eta_{t+1}G^2\mathbb{E}\left[\sum_{j=1}^d \left[(\hat{v}_{t+1}^j + \epsilon)^{-1/2} - (\hat{v}_t^j + \epsilon)^{-1/2}\right]\right]
\end{aligned} \tag{39}$$

371 Let us consider the following sequence, defined for all $t > 0$:

$$R_t := f(\theta_t) - \sum_{k=t}^{\infty} \eta_k \beta_1^{k-t+1} \mathbb{E}[\langle \nabla f(\theta_{t-1}) | (\hat{V}_t + \epsilon \mathbf{I}_d)^{-1/2} m_t \rangle] \quad (40)$$

372 We compute the following expectation:

$$\begin{aligned} \mathbb{E}[R_{t+1}] - \mathbb{E}[R_t] &= \mathbb{E}[f(\theta_{t+1}) - f(\theta_t)] - \sum_{k=t+1}^{\infty} \eta_k \beta_1^{k-t+2} \mathbb{E}[\langle \nabla f(\theta_t) | (\hat{V}_{t+1} + \epsilon \mathbf{I}_d)^{-1/2} m_{t+1} \rangle] \\ &\quad + \sum_{k=t}^{\infty} \eta_k \beta_1^{k-t+1} \mathbb{E}[\langle \nabla f(\theta_{t-1}) | (\hat{V}_t + \epsilon \mathbf{I}_d)^{-1/2} m_t \rangle] \end{aligned} \quad (41)$$

373 Using the Assumption 1, we note that:

$$\mathbb{E}[f(\theta_{t+1}) - f(\theta_t)] \leq -\eta_{t+1} \mathbb{E}[\langle \nabla f(\theta_t) | (\hat{V}_{t+1} + \epsilon \mathbf{I}_d)^{-1/2} m_{t+1} \rangle] + \frac{L}{2} \|\theta_{t+1} - \theta_t\|^2 \quad (42)$$

374 which yields

$$\begin{aligned} \mathbb{E}[R_{t+1}] - \mathbb{E}[R_t] &= -(\eta_{t+1} + \sum_{k=t+1}^{\infty} \eta_k \beta_1^{k-t+2}) \mathbb{E}[\langle \nabla f(\theta_t) | (\hat{V}_{t+1} + \epsilon \mathbf{I}_d)^{-1/2} m_{t+1} \rangle] \\ &\quad + \sum_{k=t}^{\infty} \eta_k \beta_1^{k-t+1} \mathbb{E}[\langle \nabla f(\theta_{t-1}) | (\hat{V}_t + \epsilon \mathbf{I}_d)^{-1/2} m_t \rangle] \\ &\quad + \frac{L}{2} \|\theta_{t+1} - \theta_t\|^2 \\ &\leq (\eta_{t+1} + \sum_{k=t+1}^{\infty} \eta_k \beta_1^{k-t+2}) \mathbb{E}[A_t + B_t + C_t] \\ &\quad - \sum_{k=t}^{\infty} \eta_k \beta_1^{k-t+1} \mathbb{E}[A_{t-1} + B_{t-1} + C_{t-1}] \\ &\quad + \frac{L}{2} \|\theta_{t+1} - \theta_t\|^2 \end{aligned} \quad (43)$$

375 where A_t, B_t, C_t are defined in (29).

376 We use (33) and (34) to bound A_t and B_t , and Lemma 2 to bound C_t where we precise that the
377 learning rate η_{t+1} becomes $\eta_{t+1} + \sum_{k=t+1}^{\infty} \eta_k \beta_1^{k-t+2}$. Hence

$$\begin{aligned} \mathbb{E}[R_{t+1}] - \mathbb{E}[R_t] &\leq \left((\eta_{t+1} + \sum_{k=t+1}^{\infty} \eta_k \beta_1^{k-t+2}) \beta_1 - \sum_{k=t}^{\infty} \eta_k \beta_1^{k-t+1} \right) \mathbb{E}[A_{t-1} + B_{t-1} + C_{t-1}] \\ &\quad + (\eta_{t+1} + \sum_{k=t+1}^{\infty} \eta_k \beta_1^{k-t+2}) G^2 \mathbb{E} \left[\sum_{j=1}^d \left[(\hat{v}_{t+1}^j + \epsilon)^{-1/2} - (\hat{v}_t^j + \epsilon)^{-1/2} \right]^2 \right] \\ &\quad + \left(\frac{L}{2} + (\eta_{t+1} + \sum_{k=t+1}^{\infty} \eta_k \beta_1^{k-t+2}) \frac{\beta_1 L}{\eta_{t-1}} \right) \|\theta_{t+1} - \theta_t\|^2 \\ &\quad - (\eta_{t+1} + \sum_{k=t+1}^{\infty} \eta_k \beta_1^{k-t+2}) \frac{(1 - \beta_1)}{2} \left(\epsilon + \frac{(q^2 + 1)G^2}{1 - \beta_2} \right)^{-\frac{1}{2}} \mathbb{E}[\|\nabla f(\theta_t)\|^2] \\ &\quad + q^2 \eta_{t+1} + \sum_{k=t+1}^{\infty} \eta_k \beta_1^{k-t+2} \frac{G^2}{\epsilon 2n^2} \end{aligned} \quad (44)$$

378 where the last term in the LHS is due to Lemma 3.

379 By assumption, we have that for all $t > 0$, $\eta_{t+1} \leq \eta_t$. Also, set the tuning parameters such that

$$\eta_t + \sum_{k=t}^{\infty} \eta_k \beta_1^{k-t+1} \leq \frac{\eta_t}{1 - \beta_1} \quad (45)$$

380 so that

$$\begin{aligned} & (\eta_{t+1} + \sum_{k=t+1}^{\infty} \eta_k \beta_1^{k-t+2}) \beta_1 - \sum_{k=t}^{\infty} \eta_k \beta_1^{k-t+1} = 0 \\ \iff & (\eta_{t+1} + \sum_{k=t+1}^{\infty} \eta_k \beta_1^{k-t+2}) \beta_1 = \sum_{k=t}^{\infty} \eta_k \beta_1^{k-t+1} \end{aligned} \quad (46)$$

381 Note that $-(\eta_{t+1} + \sum_{k=t+1}^{\infty} \eta_k \beta_1^{k-t+2}) \frac{(1-\beta_1)}{2} (\epsilon + \frac{(q^2+1)G^2}{1-\beta_2})^{-\frac{1}{2}} \leq -\eta_{t+1} \frac{(1-\beta_1)}{2} (\epsilon + \frac{(q^2+1)G^2}{1-\beta_2})^{-\frac{1}{2}}$
 382 since $\sum_{k=t+1}^{\infty} \eta_k \beta_1^{k-t+2} \geq 0$.

383 The above coupled with (44) yields

$$\begin{aligned} \mathbb{E}[R_{t+1}] - \mathbb{E}[R_t] & \leq -\eta_{t+1} \frac{(1-\beta_1)}{2} (\epsilon + \frac{(q^2+1)G^2}{1-\beta_2})^{-\frac{1}{2}} \mathbb{E}[\|\nabla f(\theta_t)\|^2] + q^2 \eta_{t+1} + \sum_{k=t+1}^{\infty} \eta_k \beta_1^{k-t+2} \frac{G^2}{\epsilon 2n^2} \\ & \quad - (\eta_{t+1} + \sum_{k=t+1}^{\infty} \eta_k \beta_1^{k-t+2}) G^2 \mathbb{E}[\sum_{j=1}^d [(\hat{v}_t^j + \epsilon)^{-1/2} - (\hat{v}_{t+1}^j + \epsilon)^{-1/2}]] \\ & \quad + \left(\frac{L}{2} + 1 + \frac{\beta_1 L}{1 - \beta_1} \right) \mathbb{E}[\|\theta_{t+1} - \theta_t\|^2] \end{aligned} \quad (47)$$

384 We now sum from $t = 0$ to $t = T_m - 1$ the inequality in (47), and divide it by T_m :

$$\begin{aligned} & \eta \frac{(1-\beta_1)}{2} (\epsilon + \frac{(q^2+1)G^2}{1-\beta_2})^{-\frac{1}{2}} \frac{1}{T_m} \sum_{t=0}^{T_m-1} \mathbb{E}[\|\nabla f(\theta_t)\|^2] \\ & \leq \frac{\mathbb{E}[R_0] - \mathbb{E}[R_{T_m}]}{T_m} + \frac{q^2 \eta + \sum_{k=t+1}^{\infty} \eta_k \beta_1^{k-t+2} \frac{G^2}{\epsilon 2n^2}}{T_m} \\ & \quad + \left(\frac{L}{2} + 1 + \frac{\beta_1 L}{1 - \beta_1} \right) \frac{1}{T_m} \sum_{t=0}^{T_m-1} \mathbb{E}[\|\theta_{t+1} - \theta_t\|^2] \end{aligned} \quad (48)$$

385 where we have used the fact that $(\hat{v}_t^j + \epsilon)^{-1/2} - (\hat{v}_{t+1}^j + \epsilon)^{-1/2} \geq 0$ for all dimension $j \in [d]$ by
 386 construction of \hat{v}_{t+1}^j .

387 We now bound the two remaining terms:

388 **Bounding** $-\mathbb{E}[R_{T_m}]$:

389 By definition (40) of R_t we have, using Lemma 1:

$$\begin{aligned} -\mathbb{E}[R_{T_m}] & \leq \sum_{k=t}^{\infty} \eta_k \beta_1^{k-t+1} \mathbb{E}[\langle \nabla f(\theta_{t-1}) | (\hat{V}_t + \epsilon \mathbf{I}_d)^{-1/2} m_t \rangle] - f(\theta_{T_m}) \\ & \leq \left\| \sum_{k=t}^{\infty} \eta_k \beta_1^{k-t+1} \right\| \|\nabla f(\theta_{t-1})\| \|(\hat{V}_t + \epsilon \mathbf{I}_d)^{-1/2} m_t\| \\ & \leq \eta_{t+1} (1 - \beta_1) \epsilon^{-\frac{1}{2}} \sqrt{(q^2 + 1)G^2} - f(\theta_{T_m}) \end{aligned} \quad (49)$$

390 **Bounding** $\sum_{t=0}^{T_m-1} \mathbb{E}[\|\theta_{t+1} - \theta_t\|^2]$:

391 By definition in Algorithm 1:

$$\|\theta_{t+1} - \theta_t\|^2 = \eta_{t+1}^2 \left[(\hat{V}_{t+1} + \epsilon I_d)^{-\frac{1}{2}} m_{t+1} \right]^2 = \eta_{t+1}^2 \sum_{j=1}^d \frac{|m_{t+1}^j|^2}{\hat{v}_{t+1}^j + \epsilon} \quad (50)$$

392 For any dimension $j \in [d]$,

$$\begin{aligned} |m_{t+1}^j|^2 &= |\beta_1 m_t^j + (1 - \beta_1) \bar{g}_t^j|^2 \\ &\leq \beta_1 (\beta_1^2 |m_{t-1}^j|^2 + (1 - \beta_1)^2 |\bar{g}_{t-1}^j|^2) + |\bar{g}_t^j|^2 \\ &\leq \sum_{k=0}^t \beta_1^{2(t-k)} |\bar{g}_k^j|^2 \\ &\leq \sum_{k=0}^t \frac{\beta_1^{2(t-k)}}{\beta_2^{t-k}} \beta_2^{t-k} |\bar{g}_k^j|^2 \end{aligned} \quad (51)$$

393 Using Cauchy-Schwartz inequality we obtain

$$\begin{aligned} |m_{t+1}^j|^2 &\leq \sum_{k=0}^t \frac{\beta_1^{2(t-k)}}{\beta_2^{t-k}} \beta_2^{t-k} |\bar{g}_k^j|^2 \leq \sum_{k=0}^t \left(\frac{\beta_1^2}{\beta_2} \right)^{t-k} \sum_{k=0}^t \beta_2^{t-k} |\bar{g}_k^j|^2 \\ &\leq \frac{1}{1 - \frac{\beta_1^2}{\beta_2}} \sum_{k=0}^t \beta_2^{t-k} |\bar{g}_k^j|^2 \end{aligned} \quad (52)$$

394 On the other hand we have

$$\hat{v}_{t+1}^j \geq \beta_2 \hat{v}_t^j + (1 - \beta_2) (\bar{g}_t^j)^2 \quad (53)$$

395 and since it is also true for iteration $t = 1$, we have by induction replacing v_t^j in the above that

$$\hat{v}_{t+1}^j \geq (1 - \beta_2) \sum_{k=0}^t \beta_2^{t-k} |\bar{g}_k^j|^2 \iff \frac{\sum_{k=0}^t \beta_2^{t-k} |\bar{g}_k^j|^2}{\hat{v}_{t+1}^j} \leq (1 - \beta_2)^{-1} \quad (54)$$

396 Hence, we can derive from (50) that

$$\begin{aligned} \|\theta_{t+1} - \theta_t\|^2 &= \eta_{t+1}^2 \sum_{j=1}^d \frac{|m_{t+1}^j|^2}{\hat{v}_{t+1}^j + \epsilon} \leq \eta_{t+1}^2 \sum_{j=1}^d \frac{|m_{t+1}^j|^2}{\hat{v}_{t+1}^j} \\ &\stackrel{(a)}{\leq} \eta_{t+1}^2 \sum_{j=1}^d \frac{1}{1 - \frac{\beta_1^2}{\beta_2}} \frac{\sum_{k=0}^t \beta_2^{t-k} |\bar{g}_k^j|^2}{\hat{v}_{t+1}^j} \\ &\stackrel{(b)}{\leq} \eta_{t+1}^2 d (1 - \beta_2)^{-1} \left(1 - \frac{\beta_1^2}{\beta_2}\right)^{-1} \end{aligned} \quad (55)$$

397 where (a) uses (52) and (b) uses (54).

398 Plugging the two bounds in (48), we obtain the following bound:

$$\begin{aligned} \frac{1}{T_m} \sum_{t=0}^{T_m-1} \mathbb{E}[\|\nabla f(\theta_t)\|^2] &\leq \frac{\mathbb{E}[f(\theta_0) - f(\theta_{T_m})]}{\eta \Delta_1 T_m} + \frac{q^2 \eta + \sum_{k=t+1}^{\infty} \eta \beta_1^{k-t+2} \frac{G^2}{\epsilon 2 n^2}}{\eta \Delta_1 T_m} \\ &\quad + \frac{1 - \beta_1}{\Delta_1} \epsilon^{-\frac{1}{2}} \sqrt{(q^2 + 1)} G^2 \\ &\quad + \left(\frac{L}{2} + 1 + \frac{\beta_1 L}{1 - \beta_1} \right) \frac{1}{\eta \Delta_1} \eta^2 d (1 - \beta_2)^{-1} \left(1 - \frac{\beta_1^2}{\beta_2}\right)^{-1} \end{aligned} \quad (56)$$

399 where $\Delta_1 := \frac{(1-\beta_1)}{2}(\epsilon + \frac{(q^2+1)G^2}{1-\beta_2})^{-\frac{1}{2}}$

400 With a constant stepsize $\eta = \frac{L}{\sqrt{T_m}}$ we get the final convergence bound as follows:

$$\begin{aligned} \frac{1}{T_m} \sum_{t=0}^{T_m-1} \mathbb{E}[\|\nabla f(\theta_t)\|^2] &\leq \frac{\mathbb{E}[f(\theta_0) - f(\theta_{T_m})]}{L\Delta_1\sqrt{T_m}} + d \frac{L\Delta_3}{\Delta_1\sqrt{T_m}} \\ &\quad + \frac{\Delta_2}{\eta\Delta_1 T_m} + \frac{1-\beta_1}{\Delta_1} \epsilon^{-\frac{1}{2}} \sqrt{(q^2+1)} G^2 \end{aligned} \tag{57}$$

401 where $\Delta_2 := q^2 + \sum_{k=t+1}^{\infty} \beta_1^{k-t+2} \frac{G^2}{\epsilon 2n^2}$ and $\Delta_3 := \left(\frac{L}{2} + 1 + \frac{\beta_1 L}{1-\beta_1}\right) (1-\beta_2)^{-1} (1 - \frac{\beta_1^2}{\beta_2})^{-1}$.

402 □
