

Weekly Report KARIMI 2021-07-16

This week, I have mainly focussed my work towards developing a Federated EM algorithm. Two settings are possible:

- The expectations are tractable and we want to scale to large datasets with a random data index sampling while being distributed and private (this would be a sEM method, where sEM stands for Stochastic EM).
- The expectations are not tractable and thus we would use the SAEM under the FL settings (this is the setting of the my talk from last week).

1 SAEM for Federated Learning

For computational purposes and privacy enhanced matter, I have chosen to study and develop the second algorithms that I proposed in my last week's report. In that algorithm, one does not compute a periodic averaging of the local models (this would requires performing as many M-steps as there are workers). Rather, workers compute local statistics and send them to the central server for a periodic averaging of those vectors and the latter computes one M-step to update the global model.

Algorithm 1 FL-SAEM with Periodic Statistics Averaging

- 1: **Input:** **TO COMPLETE**
- 2: Init: $\theta_0 \in \Theta \subseteq \mathbb{R}^d$, as the global model and $\bar{\theta}_0 = \frac{1}{n} \sum_{i=1}^n \theta_0$.
- 3: **for** $r = 1$ to R **do**
- 4: **for** parallel for device $i \in D^r$ **do**
- 5: Set $\hat{\theta}_i^{(0,r)} = \hat{\theta}^{(r)}$.
- 6: Draw M samples $z_{i,m}^{(r)}$ under model $\hat{\theta}_i^{(r)}$
- 7: Compute the surrogate sufficient statistics $\tilde{S}_i^{(r+1)}$
- 8: Workers send local statistics $\tilde{S}_i^{(k+1)}$ to server.
- 9: **end for**
- 10: Server computes **global model using the aggregated statistics:**

$$\hat{\theta}^{(r+1)} = \bar{\theta}(\tilde{S}^{(r+1)})$$

where $\tilde{S}^{(r+1)} = (\tilde{S}_i^{(r+1)}, i \in D_r)$ and send global model back to the devices.

- 11: **end for**
-

1.1 Challenges with Algorithm 1

While Algorithm 1 is a distributed variant of the SAEM, it is neither (a) private nor (b) communication-efficient. Indeed, we remark that broadcasting the vector of statistics are a potential breach to the data observations as their expression is related y and the latent data z . With a simple knowledge of the model used, the data could be retrieved if one extracts those statistics. Also regarding (b), the broadcast of n vector of statistics $S(y_i, z_i)$ can be cumbersome when the size of the latent space and the parameter space of the model are huge.

I am incorporating respective solutions to those problems below.

1.2 Algorithmic solutions

Line 6 – Quantization: The first step is to quantize the gradient in the Stochastic Langevin Dynamics step used in our sampling scheme Line 6 of Algorithm 1. Inspired by [1], we use an extension of the QSGD algorithm for our latent samples. Define the quantization operator as follows:

$$\mathbf{C}_j^{(\ell)}(g, \xi_j) = \|v\| \cdot \text{sign}(g_j) \cdot (\lfloor \ell |g_j| / \|v\| \rfloor + \mathbf{1}\{\xi_j \leq \ell |g_j| / \|v\| - \lfloor \ell |g_j| / \|v\| \rfloor\}) / \ell \quad (1)$$

where ℓ is the level of quantization and $j \in [d]$ denotes the dimension of the gradient.

Hence, for the sampling step, Line 6, we use the modified SGLD below, to be compliant with the privacy of our method.

Algorithm 2 Langevin Dynamics with Quantization for worker i

- 1: **Input:** Current local model $\hat{\theta}_i^{(r)}$ for worker $i \in \llbracket n \rrbracket$.
- 2: Draw M samples $\{z_i^{(r,m)}\}_{m=1}^M$ from the posterior distribution $p(z_i|y_i; \hat{\theta}_i^{(k)})$ via Langevin diffusion with a quantized gradient:
- 3: **for** $k = 1$ to K **do**
- 4: Compute the quantized gradient of $\nabla \log p(z_i|y_i; \hat{\theta}_i^{(k)})$:

$$g_i(k, m) = \mathbf{C}_j^{(\ell)}\left(\nabla_j f_{\theta_i}(z_i^{(k-1,m)}), \xi_j^{(k)}\right) \quad (2)$$

where $\xi_j^{(k)}$ is a realization of a uniform random variable.

- 5: Sample the latent data using the following chain:

$$z_i^{(k,m)} = z_i^{(k-1,m)} + \frac{\gamma_k}{2} g_i(k, m) + \sqrt{\gamma_k} \mathbf{B}_k, \quad (3)$$

where \mathbf{B}_t denotes the Brownian motion.

- 6: **end for**
 - 7: Assign $\{z_i^{(r,m)}\}_{m=1}^M \leftarrow \{z_i^{(K,m)}\}_{m=1}^M$.
 - 8: **Output:** latent data $z_{i,m}^{(k)}$ under model $\hat{\theta}_i^{(t,k)}$
-

Line 7 – Compression MCMC output: We use the notorious **Top- k** operator that we define as $\mathcal{C}(x)_i = x_i$, if $i \in \mathcal{S}$; $\mathcal{C}(x)_i = 0$ otherwise and where \mathcal{S} is defined as the size- k set of $i \in [p]$. Recall that after Line 6 we compute the local statistics $\tilde{S}_i^{(k+1)}$ using the output latent variables from Algorithm 2. We now use those statistics and compress them using Algorithm 3 as follows:

Algorithm 3 Sparsified Statistics with **Top- k**

- 1: **Input:** Current local statistics $\tilde{S}_i^{(k+1)}$ for worker $i \in \llbracket n \rrbracket$. Sparsification level k .
- 2: Apply **Top- k** :

$$\ddot{S}_i^{(k+1)} = \mathcal{C}\left(\tilde{S}_i^{(k+1)}\right) \quad (4)$$

- 3: **Output:** Compressed local statistics for worker i denoted $\ddot{S}_i^{(k+1)}$.
