Abstract

1   To be completed

1   Notations

3   We minimize the negated log incomplete data likelihood

$$\min_{\theta \in \Theta} \overline{L}(\theta) := L(\theta) + r(\theta) \quad \text{with} \; L(\theta) = \frac{1}{n}\sum_{i=1}^{n} L_i(\theta) := \frac{1}{n}\sum_{i=1}^{n}\big\{-\log g(y_i;\theta)\big\} , \quad (1)$$

4   Here, nn denotes the number of worker in the decentralized and federated settings.

5   Consider a curved exponential family

$$f(z_i, y_i; \theta) = h(z_i, y_i)\exp(\langle S(z_i, y_i) \,|\, \phi(\theta)\rangle - \psi(\theta)) , \quad (2)$$

6   Then EM reads

$$\overline{s}_i(\theta) := \int_{\mathsf{Z}} S(z_i, y_i) p(z_i|y_i;\theta)\mu(\mathrm{d}z_i) , \quad (3)$$

7   and the *M-step* is given by

$$\overline{\theta}(\overline{s}(\theta)) := \underset{\vartheta \in \theta}{\arg\min} \; \big\{ \mathrm{R}(\vartheta) + \psi(\vartheta) - \langle \overline{s}(\theta) \,|\, \phi(\vartheta)\rangle \big\} . \quad (4)$$

8   In the case where the expectations are intractable, then (3) becomes:

$$\tilde{S}^{(k+1)} := \frac{1}{n}\sum_{i=1}^{n} \tilde{S}_i^{(k+1)} = \frac{1}{n}\sum_{i=1}^{n}\frac{1}{M_k}\sum_{m=1}^{M_k} S(z_{i,m}^{(k)}, y_i) , \quad (5)$$

2 Algorithms

For computational purposes and privacy enhanced matter, I have chosen to study and develop the second algorithms that I proposed in my last week's report. In that algorithm, one does not compute a periodic averaging of the local models (this would requires performing as many M-steps as there are workers). Rather, workers compute local statistics and send them to the central server for a periodic averaging of those vectors and the latter computes one M-step to update the global model.

Algorithm 1 FL-SAEM with Periodic Statistics Averaging

1: **Input**: TO COMPLETE
2: Init: $\theta_0 \in \Theta \subseteq \mathbb{R}^d$, as the global model and $\bar{\theta}_0 = \frac{1}{n} \sum_{i=1}^n \theta_0$.
3: **for** $r = 1$ to R **do**
4:     **for** parallel for device $i \in D^r$ **do**
5:         Set $\hat{\theta}_i^{(0,r)} = \hat{\theta}^{(r)}$.
6:         Draw M samples $z_{i,m}^{(r)}$ under model $\hat{\theta}_i^{(r)}$
7:         Compute the surrogate sufficient statistics $\tilde{S}_i^{(r+1)}$
8:         Workers send local statistics $\tilde{S}_i^{(k+1)}$ to server.
9:     **end for**
10:    Server computes **global model using the aggregated statistics**:

$$\hat{\theta}^{(r+1)} = \overline{\theta}(\tilde{S}^{(r+1)})$$

      where $\tilde{S}^{(r+1)} = (\tilde{S}_i^{(r+1)}, i \in D_r)$ and send global model back to the devices.
11: **end for**

2.1 Challenges with Algorithm 4

While Algorithm 4 is a distributed variant of the SAEM, it is neither (a) *p*rivate nor (b) *c*ommunication-efficient.

Privacy: Indeed, we remark that broadcasting the vector of statistics are a potential breach to the data observations as their expression is related y and the latent data z. With a simple knowledge of the model used, the data could be retrieved if one extracts those statistics.

Communication bottlenecks: Also regarding (b), the broadcast of n vector of statistics $S(y_i, z_i)$ can be cumbersome when the size of the latent space and the parameter space of the model are huge.

2.2 Algorithmic solutions

Line 6 – Quantization: The first step is to quantize the gradient in the Stochastic Langevin Dynamics step used in our sampling scheme Line 6 of Algorithm 4. Inspired by [Alistarh et al., 2017], we use an extension of the QSGD algorithm for our latent samples. Define the quantization operator as follows:

$$\mathsf{C}_j^{(\ell)}(g, \xi_j) = \|v\| \cdot \mathrm{sign}(g_j) \cdot (\lfloor \ell |g_j| / \|v\| \rfloor + \mathbf{1}\{\xi_j \leq \ell |g_j| / \|v\| - \lfloor \ell |g_j| / \|v\| \rfloor\}) / \ell \quad (6)$$

where ℓ is the level of quantization and $j \in [d]$ denotes the dimension of the gradient.

Hence, for the sampling step, Line 6, we use the modified SGLD below, to be compliant with the privacy of our method.

Algorithm 2 Langevin Dynamics with Quantization for worker i

1: **Input**: Current local model $\hat{\theta}_i^{(r)}$ for worker $i \in [\![1, n]\!]$.
2: Draw M samples $\{z_i^{(r,m)}\}_{m=1}^M$ from the posterior distribution $p(z_i|y_i; \hat{\theta}_i^{(k)})$ via Langevin diffusion with a quantized gradient:
3: **for** $k = 1$ to K **do**
4:     Compute the quantized gradient of $\nabla \log p(z_i|y_i; \hat{\theta}_i^{(k)})$:

$$g_i(k, m) = \mathsf{C}_j^{(\ell)} \left(\nabla_j f_{\theta_t}(z_i^{(k-1,m)}), \xi_j^{(k)} \right) \tag{7}$$

where $\xi_j^{(k)}$ is a realization of a uniform random variable.
5:     Sample the latent data using the following chain:

$$z_i^{(k,m)} = z_i^{(k-1,m)} + \frac{\gamma_k}{2} g_i(k, m) + \sqrt{\gamma_k} \mathsf{B}_k , \tag{8}$$

where B_t denotes the Brownian motion and $m \in [M]$ denotes the MC sample.
6: **end for**
7: Assign $\{z_i^{(r,m)}\}_{m=1}^M \leftarrow \{z_i^{(K,m)}\}_{m=1}^M$.
8: **Output:** latent data $z_{i,m}^{(k)}$ under model $\hat{\theta}_i^{(t,k)}$

Line 6 – Compression MCMC output: We use the notorious **Top-**k operator that we define as $\mathcal{C}(x)_i = x_i$, if $i \in \mathcal{S}$; $\mathcal{C}(x)_i = 0$ otherwise and where $\mathcal{S}$ is defined as the size-k set of $i \in [p]$. Recall that after Line 6 we compute the local statistics $\tilde{S}_i^{(k+1)}$ using the output latent variables from Algorithm 2. We now use those statistics and compress them using Algorithm 3 as follows:

Algorithm 3 Sparsified Statistics with **Top-**k

1: **Input**: Current local statistics $\tilde{S}_i^{(k+1)}$ for worker $i \in [\![1, n]\!]$. Sparsification level k.
2: Apply **Top-**k:

$$\ddot{S}_i^{(k+1)} = \mathcal{C}\left(\tilde{S}_i^{(k+1)} \right) \tag{9}$$

3: **Output:** Compressed local statistics for worker i denoted $\ddot{S}_i^{(k+1)}$.

---

3 FL and Distributed Algorithmic Contributions

Final method:

Algorithm 4 Quantized and Compressed FL-SAEM with Periodic Statistics Averaging

---

1: **Input**: Compression operator $\mathcal{C}(\cdot)$, number of rounds R, initial parameter θ_0.
2: **for** $r = 1$ to R **do**
3:     **for** parallel for device $i \in D^r$ **do**
4:         Set $\hat{\theta}_i^{(0,r)} = \hat{\theta}^{(r)}$. {Initialize each worker with current global model}
5:         Draw M samples $z_{i,m}^{(r)}$ under model $\hat{\theta}_i^{(r)}$ via Quantized LD: {Local Quantized MCMC step}
6:         **for** $k = 1$ to K **do**
7:             Compute the quantized gradient of $\nabla \log p(z_i|y_i; \hat{\theta}_i^{(k)})$:

$$g_i(k,m) = \mathsf{C}_j^{(\ell)} \left(\nabla_j f_{\theta_t}(z_i^{(k-1,m)}), \xi_j^{(k)} \right) \quad \text{where} \quad \xi_j^{(k)} \sim \mathcal{U}_{[a,b]}$$

8:             Sample the latent data using the following chain:

$$z_i^{(k,m)} = z_i^{(k-1,m)} + \frac{\gamma_k}{2} g_i(k,m) + \sqrt{\gamma_k}\mathsf{B}_k,$$

            where B_t denotes the Brownian motion and $m \in [M]$ denotes the MC sample.
9:         **end for**
10:        Assign $\{z_i^{(r,m)}\}_{m=1}^M \leftarrow \{z_i^{(K,m)}\}_{m=1}^M$.
11:        Compute $\tilde{S}_i^{(r+1)}$ and its **Top-**k variant $\ddot{S}_i^{(r+1)} = \mathcal{C}\left(\tilde{S}_i^{(r+1)} \right)$. {Compressed local statistics}
12:        Worker send local statistics $\tilde{S}_i^{(r+1)}$ to server. {Single round of communication}
13:     **end for**
14:     Server computes **global model**: {(Global) M-Step using aggregated statistics}

$$\hat{\theta}^{(r+1)} = \overline{\theta}(\ddot{S}^{(r+1)})$$

    where $\ddot{S}^{(r+1)} = (\ddot{S}_i^{(r+1)}, i \in D_r)$ and send global model back to the devices.
15: **end for**

We can also consider the plain distributed version of the sEM which does not tackle any privacy or communication bottlenecks. It goes as follows:

Algorithm 5 Distributed SAEM with Periodic Locals Models Averaging

---

1: **Input**: Compression operator $\mathcal{C}(\cdot)$, number of rounds R, initial parameter θ_0.
2: **for** $r = 1$ to R **do**
3:     **for** parallel for device $i \in D^r$ **do**
4:         Set $\hat{\theta}_i^{(r)} = \hat{\theta}^{(r)}$. {Initialize each worker with current global model}
5:         Draw M samples $z_{i,m}^{(r+1)}$ under model $\hat{\theta}_i^{(r)}$ via MCMC: {Local MCMC step}
6:         Compute the local statistics $\tilde{S}_i^{(r+1)} = S(z_{i,m}^{(r+1)})$. {Local statistics}
7:         Worker computes **local model**: {(Local) M-Step using local statistics}

$$\hat{\theta}_i^{(r+1)} = \overline{\theta}(\tilde{S}_i^{(r+1)})$$

8:         Worker sends local model $\hat{\theta}_i^{(r+1)}$ to server.
9:     **end for**
10:     Server computes **global model** by periodic averaging {Local model averaging}

$$\hat{\theta}^{(r+1)} := \frac{1}{n} \sum_{i=1}^n \hat{\theta}_i^{(r+1)}$$

11: **end for**

---

4 Theoretical Findings

5 Numerical Experiments

5.1 Nonlinear Mixed Models under Distributed Settings

Compare SAEM, MCEM, dist-SAEM and maybe one distributed Gradient Descent as baseline

Same for Private settings with Sketched SGD or another good baseline

5.2 Probabilistic Latent Dirichlet Allocation
